REPORTED PROBLEM:

The topside panel has unresponsive buttons.

SYSTEM VOLTAGE:

• 120\

PROBABLE CAUSES:

- Damaged topside panel.
- Faulty connection between the topside panel and system pack circuit board.
- Faulty service voltage

TROUBLE SHOOTING STRATEGY:

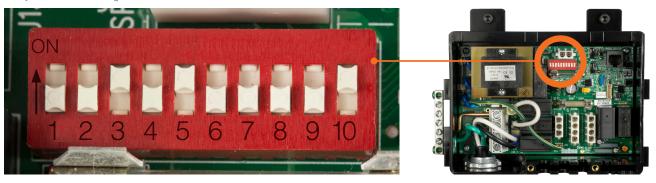

- Verify DIP switches are set to factory default settings.
- Check connection between the topside panel and system pack circuit board.
- Verify voltage at the system pack terminal block
- Put the system in Priming Mode and test the panel buttons.
 The system is in Priming Mode when the topside panel displays "Pr."

IMPORTANT TROUBLESHOOTING CONCEPTS:

- The wire diagram shows factory default DIP switch settings.
 Before you start troubleshooting, make sure the DIP switches
 on the circuit board match factory default settings. Why is this
 important? When the system is in factory default mode, the
 spa technician will know how the system should behave, which
 makes troubleshooting easier.
- DO NOT change DIP switch settings when the system is powered ON. The only exception is DIP switch #1.
- After you change DIP switch settings (except for switch #1), you need to reset persistent memory for the changes to take effect.
 If persistent memory is not reset, the system may malfunction.

Verify DIP switches have factory default settings before troubleshooting. If the DIP switches do not have factory default settings, go to step 5. DO NOT change DIP switch settings when the system is powered ON. The only exception is DIP switch #1.

Factory default DIP switch settings

HIGH AMP - HEAT W/P1 HI	10	LOW AMP - NO HEAT W/P1 HI		ADD LINE 2

Use a voltmeter to verify voltage at the terminal block.

Set the volt meter to AC voltage for steps 2 - 4. "AC" stands for alternating current.

Voltage measurements that vary plus or minus 10% are accurate. For example, if a 120V component is measured between 108V - 132V, the reading is accurate.

Measurements 1 and 2 should be 120V.

If they are 120V, go to step 4.

If they are not 120V, there may be problems with the GFCI cord or electrical outlet. Go to step 5.

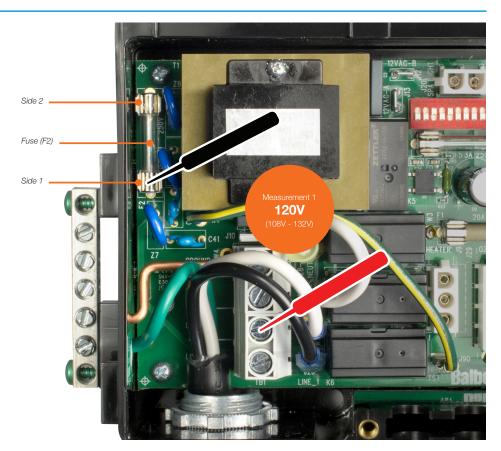

Verify the fuse (F2) is good by measuring voltage between the terminal block and the fuse. Set the volt meter to AC voltage. Measure voltage on both sides of the fuse.

Measurement 1

This determines if voltage is flowing from the terminal block to the fuse.

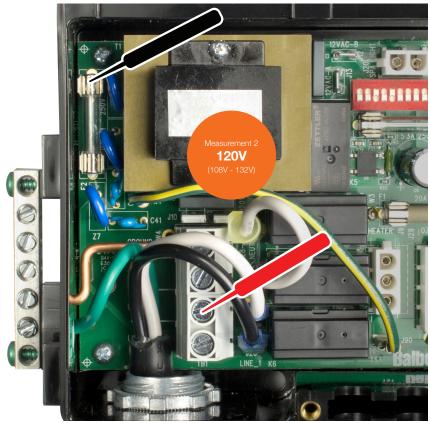

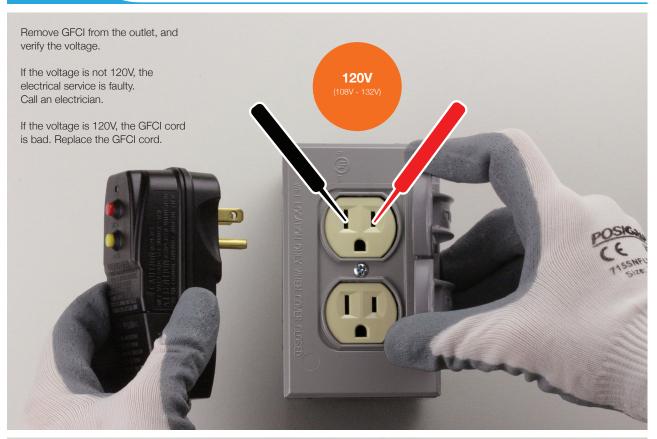

Measurement 2

This determines if the fuse is good.

If measurement 2 is approximately zero volts, the fuse is bad. Replace it.

If measurement 2 is 120V, the fuse is good, but the system pack is bad. Replace the system pack.

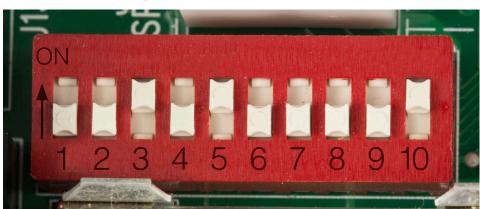

Follow these steps to apply factory default DIP switch settings.

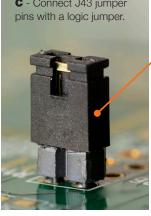

A - Power OFF the system by unplugging the GFCI cord from the wall outlet.

B - Apply factory default setting to the DIP switches.

C - Connect J43 jumper pins with a logic jumper.

D - Power ON the system by plugging the GFCI cord into the wall outlet, and wait until "Pr" appears on the topside panel. "Pr" stands for priming mode.

A - Once the system is powered ON, it should go into Priming Mode ("Pr") automatically.

B - When "Pr" appears on the topside panel display, the system is in Priming Mode. Push the Jets and/or Light buttons to verify operation. Next, press the temperature buttons to verify operation. If the buttons do not work properly, replace the topside panel. If the buttons work properly, there may be an intermittent problem. Go to step C.

C - Power OFF the system at the GFCI, and disconnect the topside panel from the system circuit board at J1. Make sure the connectors are free of dust, corrosion, residue, etc. Reconnect the panel, and power ON the system. If the panel buttons do not function properly, replace the topside panel.

STEP 7

A - Power OFF the system by unplugging the GFCI cord from the wall outlet.
